

Geospatial Area Report

Lipa, Batangas, Philippines

Key Statistics

Metric	Value
Area	211.27 km²
Total Points of Interest	3001
Distinct Categories	73
Intersection Density	49.6 per km²
Total Street Length	1281.52 km
Street Density	6.07 km per km²

Top 5 Points of Interest Categories

Category	Count
parking_space	1607

parking	396
restaurant	127
school	124
fast_food	115

Analysis & Insights

The data for Lipa, Batangas, Philippines reveals a distinct urban character that is largely car-dependent. With a total of 3001 points of interest, the top two categories are parking spaces and parking, accounting for 2003 out of 3001, or approximately 66% of all points of interest. This suggests that the area is designed to accommodate a high volume of vehicular traffic, with a significant emphasis on parking infrastructure. The prevalence of parking facilities is further reinforced by the relatively low intersection density of 49.6 per km², which may indicate a more sprawling, low-density development pattern.

One of the most interesting findings is the dominance of parking-related points of interest in the area. The fact that parking spaces and parking lots account for over 66% of all points of interest is notable, and suggests that the area may be prioritizing the needs of drivers over other modes of transportation. In contrast, categories such as restaurant, school, and fast food, which are often associated with more walkable, mixed-use environments, are relatively underrepresented. For example, restaurants account for only 127 points of interest, or approximately 4% of the total.

The data also has implications for urban planning in Lipa, Batangas. The low intersection density and high percentage of parking-related points of interest may indicate a lack of pedestrian-friendly infrastructure and a reliance on personal vehicles. This could have negative consequences for traffic congestion, air quality, and public health. Furthermore, the circuitry value of 1.0935, which indicates that streets are slightly more circuitous than a perfectly straight line, may suggest opportunities for improving the efficiency and navigability of the street network. By prioritizing more mixed-use development and investing in pedestrian-friendly infrastructure, urban planners may be able to create a more sustainable and livable environment for residents.

The street density of 6.07 km per km², while not extremely high, does provide a foundation for creating more compact, walkable neighborhoods. However, this would require a shift in focus away from accommodating vehicular traffic and towards creating more people-friendly public spaces. By rethinking the balance between parking infrastructure and other land uses, urban planners in Lipa, Batangas may be able to create a more vibrant, diverse, and sustainable urban environment that supports the needs of all residents, not just drivers.
